Sticky Policies in OWL2: Extending $\mathcal{PL}$ with Fixpoints and Transitive Closure

Piero A. Bonatti, Luigi Sauro,
Università di Napoli Federico II
{pab, luigi.sauro}@unina.it

Abstract

$\mathcal{PL}$ is a low-complexity profile of OWL2, expressly designed to encode data usage policies and personal data protection regulations - such as the GDPR - in a machine understandable way. With $\mathcal{PL}$, the compliance of privacy policies with the GDPR and with the data subjects’ consent to processing can be checked automatically and in real time. In this paper, we extend $\mathcal{PL}$ to support "sticky policies". They are a sort of license that applies to data transfers, and specifies how the recipient can use the data. Sticky policies may be "recursive", i.e. they may apply not only to the first data transfer, but also to all subsequent transfer operations that the (direct or indirect) recipients may execute in the future. Recursive sticky policies can be encoded with fixpoints or transitive role closure. In this paper we prove that such extensions make compliance checking intractable. Since the scalability of compliance checking is a major requirement in this area, these results justify a specialized, polynomial-time approach to encoding sticky policies.

1 Introduction

The European General Data Protection Regulation (GDPR) has changed the landscape of personal data processing. Due to the heavy sanctions and reputation loss incurred in case of violations, the legal entities that process personal data (controllers in GDPR’s terminology), are calling for automated support to compliance. The European H2020 projects SPECIAL\footnote{https://specialprivacy.ercim.eu/} and TRAPEZE\footnote{https://trapeze-project.eu/} tackle this need by means of semantic technologies, that effectively yield reliability, interoperability, extensibility, flexibility, usability and scalability (Bonatti, Sauro, and Langens 2021). In particular, usability and scalability have been addressed in SPECIAL by identifying a profile of OWL2, called OWL2-PL (policy language), that is simpler to grasp for users with no background in logic, and can be processed very efficiently using specialized reasoners (Bonatti et al. 2020). The description logic corresponding to OWL2-PL is called $\mathcal{PL}$. One of the goals of TRAPEZE is extending $\mathcal{PL}$ with additional constructs, so as to support more general use cases. In this paper we focus on extending $\mathcal{PL}$ to support sticky policies. They are a sort of license that applies to data transfers, and specifies how direct and indirect recipients can use the data. Before delving into technical details, let us summarize the basic features of the semantic policy framework of SPECIAL and TRAPEZE that we are going to enrich.

A (privacy) policy $P$ complies with a policy $P'$ (a consent statement or regulation) if, and only if, all the operations authorized by $P$ are also authorized by $P'$, that is, $P$ is a subclass of $P'$. Thus, compliance checking is naturally reduced to subsumption checking in description logic. For example, if Email is a subclass of Contact (contact data) and Advertising a subclass of Marketing, then the above policy complies with the consent to transferring contact data to third parties for advertising purposes, which is formalized as:

\[
\exists \text{has\_data\_Contact} \quad \exists \text{has\_processing\_Transfer} \quad \exists \text{has\_purpose\_Marketing} .
\]

Note that the classical semantics of subsumption checking (based on entailment) treats policies as closed policies, that is, only what is explicitly allowed is permitted. For example, a privacy policy whose purpose is not subsumed by Marketing would not comply with the above consent statement.
Data transfers can be constrained with sticky policies. For instance, the above consent statement can be refined to state that third parties are allowed (only) to directly use the data subject’s contact information for marketing purposes (which implicitly forbids further transfers to third parties, if we assume that Transfer is not subsumed by DirectUse):

\[
\exists \text{has\_data.\ Contact} \sqsubseteq \\
\exists \text{has\_processing.\ Transfer} \sqsubseteq \\
\exists \text{has\_purpose.\ Marketing} \sqsubseteq \\
\text{sticky}. \\
\exists \text{has\_data.\ Contact} \sqsubseteq \\
\exists \text{has\_processing.\ DirectUse} \sqsubseteq \\
\exists \text{has\_purpose.\ Marketing} .
\]

Property “sticky” should be functional in order to avoid the ambiguities that may arise from the application of different, overlapping policies.

By nesting sticky policies, one may allow further transfers to third parties, as in the following expression:

\[
P_0 \sqsubseteq \exists \text{sticky}. (P_1 \sqsubseteq \exists \text{sticky}. (P_2 \sqsubseteq \ldots \exists \text{sticky}. P_n \sqsubseteq \ldots)).
\]

Here the controller should satisfy \(P_0\), while its direct recipients have to satisfy \(P_1\); in turn, their recipients should satisfy \(P_2\), and so on. Clearly, the above concept regulates only finite disclosure chains of length \(n\). In general, however, disclosure chains can be unbounded. Then sticky policies should be recursive, that is, they should identically apply to all (direct and indirect) recipients, and allow each of them to further transfer data to other third parties. Formally, one would like to express something like the infinitary concept

\[
P_0 \sqsubseteq \exists \text{sticky}. (P_1 \sqsubseteq \exists \text{sticky}. (P_1 \sqsubseteq \exists \text{sticky}. (P_1 \sqsubseteq \ldots))).
\]

Logic provides at least two ways of expressing the above class with a finite expression: greatest fixpoint operators (\(\nu\) and transitive role closure (\(R^+\)). Since sticky is a functional property, the following are equivalent to the above concept:

\[
P_0 \sqsubseteq \nu X. (\exists \text{sticky}. (P_1 \sqsubseteq X) ,
\]

\[
P_0 \sqsubseteq (\exists \text{sticky}. P_1) \sqsubseteq \forall \text{sticky}^+. (\exists \text{sticky}. P_1).
\]

Accordingly, in this paper, we are going to investigate the extensions of \(\mathcal{PL}\) with greatest fixpoints, universal quantifiers, and transitive role closure. The ultimate goal is supporting sticky policies in a very efficient manner, as some of the use cases of interest to the industrial partners of SPECIAL and TRAPEZE require to complete thousands of compliance checks per second.

**Example 1** (Streaming Scenario). Telecom providers, that today are also Internet providers, receive from their base stations about 15000 call records per second, and almost 10000 probing records per second from their wi-fi network. The data contained in the aforementioned records are of great interest for strategic applications and services, such as location-based services and tailored recommendations; however, call and probing records contain personal data, and the European regulation on data protection prohibits the above usage without the consent of the data subjects. Without consent, even storing the data temporarily, waiting for a batch process to discard the records that cannot be processed, is illegal. Then the description of how and why each application processes the data must be checked in real-time for compliance with the consent statements that apply to the records being processed. This scenario is further complicated by the fact that each data subject can withdraw or modify her consent anytime, and that she may selectively decide to opt in or out each processing option (e.g. a customer might accept only location tracking, and not internet tracking).

More generally, subsumption checks are going to be as frequent as access control checks in our target applications. Therefore, the semantic policy framework must satisfy extreme scalability requirements, that are not common in the knowledge representation area. Thus, an implied necessary requirement is that subsumption checking must be possible in deterministic polynomial time, and the degree of the polynomial should be low.

In (Bonatti et al. 2020), it has been proved – both theoretically and experimentally – that \(\mathcal{PL}\) satisfies the scalability requirement, and that real policies can be checked for compliance in a few hundreds of \(\mu\)-seconds using a sequential Java implementation (i.e. a technology that is not intrinsically performant). The challenge now is supporting sticky policies while preserving the performance of \(\mathcal{PL}\).

In sections 3 and 4 we prove that the extensions of \(\mathcal{PL}\) with \(\nu\) and with the combination of \(\forall\) and transitive role closure – respectively – are intractable. We prove lower complexity bounds at the first level of the polynomial hierarchy; they suffice to conclude that the above extensions of \(\mathcal{PL}\) are not suitable for our purposes. Concerning upper complexity bounds, the complexity of the logics supporting \(\nu\) and transitive role closure is typically much higher, namely, EXPTIME or harder, if a full set of boolean operators is supported. In our setting, getting a tighter complexity estimate is difficult, due to the limited expressiveness of \(\mathcal{PL}\); this aspect is further detailed in section 6.

The intractability results justify a tractable approach tailored to the use cases, based on a restricted language \(\mathcal{PL}^{\text{sticky}}\) that will be illustrated in section 5. This language preserves the asymptotic complexity of reasoning of \(\mathcal{PL}\), so it is a promising approach to sticky policy representation.

The basic notions about description logics and \(\mathcal{PL}\) are recalled in the next section. Related and future works are discussed in section 6.

**2 Preliminary Definitions**

We assume the reader to be familiar with the basic notions of Description Logics (DL) (Baader et al. 2003). Here we recall only the aspects needed for this work. The DL languages of our interest are built from countably infinite sets of concept names (\(N_C\)), role names (\(N_R\)), and concrete property names (\(N_P\)). An interpretation \(I\) is a structure \(I = (\Delta^I, \mathcal{I})\) where \(\Delta^I\) is a nonempty set, and the interpretation function \(\mathcal{I}\) is such that (i) \(A^I \subseteq \Delta^I\) if \(A \in N_C\); (ii) \(R^I \subseteq \Delta^I \times \Delta^I\) if \(R \in N_R\); (iii) \(f^I \subseteq \Delta^I \times N\) if \(f \in N_F\), where \(N\) denotes the set of natural numbers.

Compound concepts and roles are built from concept names, role names, and the logical constructors listed in Ta-

$\mathcal{P}L$ axiom $\alpha$          $\mathcal{I} \models \alpha$ iff:

$A \sqsubseteq B$                $A^2 \subseteq B^2$
$A_1 \sqcap \cdots \sqcap A_n \sqsubseteq B$  $A_1^2 \sqcap \cdots \sqcap A_n^2 \subseteq B^2$
$\operatorname{disj}(A, B)$  $A^2 \sqcap B^2 = \emptyset$
$\operatorname{range}(R, A)$                $(x, y) \in R^2 \rightarrow y \in A^2$
$\operatorname{func}(R)$                 $(x, y) \in R^2 \land (x, z) \in R^2 \rightarrow y = z$

$\mathcal{P}L$ with Fixpoints

Let $\mathcal{P}L_0$ be the extension of $\mathcal{P}L_0$ where greatest fixpoints may occur in subsumption queries. At a first glance, $\mathcal{P}L_0$ constitutes a promising way of encoding sticky policies, due to its similarity with $\mathcal{E}L$ with greatest fixpoints, that has been proved to be tractable in (Lutz, Piro, and Wolter 2010).

However, the interplay of greatest fixpoints with functional roles (that are supported only in $\mathcal{P}L$) makes subsumption checking at least coNP-hard. This holds not only for concepts ($\mathcal{P}L$’s subsumption queries are inclusions $C \sqsubseteq D$ where $C, D$ are full $\mathcal{P}L$ concepts. A $\mathcal{P}L$ subsumption query $C \sqsubseteq D$ is simple if both $C$ and $D$ are simple.

If $KB$ entails a subsumption query $C \sqsubseteq D$ (in symbols, $KB \models C \sqsubseteq D$), then we say that $C$ complies with $D$ (under $KB$). Compliance checking is in general coNP-complete, however it downgrades to $\mathcal{P}$ whenever the query $C \sqsubseteq D$ is interval safe, that is: for all interval constraints $\exists f, [l, u] \in C^2$ and $\exists f', [l', u'] \in C^2$ occurring in $C$ and $D$, respectively, either $[l, u] \subseteq [l', u']$ or $[l, u] \cap [l', u'] = \emptyset$ (Bonatti et al. 2020).

Notably, coming back to the general case where $C$ and $D$ may contain partially overlapping intervals, and $C = C_1 \sqcup \cdots \sqcup C_n$, it is always possible to turn $C \sqsubseteq D$ into an equivalent, interval safe query by splitting the intervals of $C$ in a suitable way. The resulting concept $C'$ has size $O(|C| \cdot |D|^2)$, where $c = \max_{1 \leq i \leq n} c_i$ and each $c_i$ is the number of interval constraints occurring in $C_i$, for $i = 1, \ldots, n$. Fortunately, the exponent $c$ is a fixed constant in our use cases, therefore, $C'$ can be computed in polynomial time and compliance checking is tractable. In particular, policy encoding requires at most one interval constraint per simple concept (such interval is used to specify how long data are kept by the controller). In the following, no more details about these complexity issues will be needed; the interested reader is referred to (Bonatti et al. 2020) for a complete discussion.

Hereafter, in order to keep different sources of complexity cleanly separated in the complexity analysis, we consider (and extend) the restricted logic $\mathcal{P}L_0$ obtained from $\mathcal{P}L$ by disallowing interval constraints – therefore, in $\mathcal{P}L_0$, subsumptions are vacuously interval safe, and subsumption checking is tractable. $\mathcal{P}L$ will be considered again in section 6.

Next, let us define the greatest fixpoint operator $\nu$ that will be used in section 3 to augment the query language. To this aim, we consider a supplementary countably infinite set $\mathbb{N}_V$ of variables; similarly to an atomic concept, a variable $X$ is interpreted as a set of individuals, $X^2 \subseteq \Delta^2$. Let $E$ be a subset of $\Delta^2$; by $I[X \rightarrow E]$ we mean the interpretation such that $X$ is interpreted as $E$, and all the other symbols are interpreted as in $\mathcal{I}$. Then, the semantics of a fixpoint concept $\nu X.C$ is the following:

$\{\nu X.C\}^2 = \bigcup\{E \subseteq \Delta^2 \mid E \subseteq C^2[X \rightarrow E]\}$

Finally, a pointed interpretation is a pair $\mathcal{I}, d$, where $d \in \Delta^2$. We say that $\mathcal{I}, d$ satisfies a concept $C$ (in symbols, $\mathcal{I}, d \models C$) iff $d \in C^2$. We also say that $\mathcal{I}, d$ is a model of a knowledge base $KB$ if $\mathcal{I} \models KB$. 

3 $\mathcal{P}L$ with Fixpoints

Let $\mathcal{P}L_0'$ be the extension of $\mathcal{P}L_0$ where greatest fixpoints may occur in subsumption queries. At a first glance, $\mathcal{P}L_0'$ constitutes a promising way of encoding sticky policies, due to its similarity with $\mathcal{E}L$ with greatest fixpoints, that has been proved to be tractable in (Lutz, Piro, and Wolter 2010).
$\mathcal{PL}$, but also for all the description logics that support $\land$, $\lor$, and $\func$ in knowledge base axioms, and $\forall$, $\exists$, and $\nu$ in subsumption queries.

**Theorem 2.** Let $\mathcal{DL}$ be any description logics that supports $\land$, $\lor$, and $\func$ in knowledge base axioms, and $\forall$, $\exists$, and $\nu$ in subsumption queries. Subsumption checking in $\mathcal{DL}$ is coNP-hard.

**Proof.** The proof is by reduction of the validity problem to subsumption checking. Let $\phi = \bigvee_{i=1}^{m} \ell_{i,1} \land \ell_{i,2} \land \ell_{i,3}$ be any propositional formula in 3-DNF, and let $x_1, \ldots, x_k$ be the propositional variables occurring in $\phi$. Introduce a fresh concept name $A_i$ for each $x_i$ and a fresh concept name $A_0$ for each negative literal $\neg x_i$. For each propositional literal $\ell$, let $\ell$ denote the corresponding concept name. Informally speaking, the knowledge base $KB$ encodes $\phi$ in such a way that if an individual $d$ satisfies $\phi$ (up to the correspondence between literals and concepts), then $d$ satisfies also a distinguished atomic concept $F$ that represents the truth of $\phi$. More formally, let $KB$ consist of the following axioms, where each concept $B_i$ represents the truth of the $i$-th disjunct of $\phi$:

$$
\begin{align*}
&\ell_{i,1} \land \ell_{i,2} \land \ell_{i,3} \subseteq B_i \\
&B_i \subseteq F \\
&\func(R)
\end{align*}
$$

(where $i = 1, \ldots, m$). The use of role $R$ will be explained later.

Greatest fixpoints are used to create periodic chains of instance types. To make this more precise, we need some auxiliary definitions. First, for all $i = 1, \ldots, k$ (where $k$ is the number of propositional variables in $\phi$), define:

$$
\begin{align*}
&C_i^1 = A_i \land \exists R.X \\
&C_i^{j+1} = \neg A_i \land \exists R.C_i^j
\end{align*}
$$

(where $X$ is a concept variable). For example,

$$
\begin{align*}
&C_i^2 = \neg A_i \land \exists R.(A_i \land \exists R.X) \\
&C_i^3 = \neg A_i \land \exists R.(\neg A_i \land \exists R.(A_i \land \exists R.X)) \\
&C_i^4 = \neg A_i \land \exists R.(\neg A_i \land \exists R.(\neg A_i \land \exists R.(A_i \land \exists R.X)))
\end{align*}
$$

Note that the instances of any concept $\nu X.C_i^j$ are the first elements of infinite $R$-chains where $A_i$ is satisfied (at least) every $j$ steps, while the other elements satisfy (at least) $A_i$. Let $p_1 = 2, p_2 = 3, p_3 = 5, \ldots, p_k$ be the first $k$ prime numbers, and define:

$$
C = \prod_{i=1}^{k} \nu X.C_i^{p_i}.
$$

**Claim:** $\phi$ is valid iff $KB |= C \subseteq \nu X.(F \land \exists R.X).

First we prove the "only if" part of the claim. If $\phi$ is valid, then for all models $I$ of $KB$ and all individuals $d \in \Delta^2$, the following clearly holds: If $d$ belongs to $A_i^2$ or $A_i^2$ for all $i = 1, \ldots, k$, then $d \in F^2$. Note that $C$ forces all the direct and indirect $R$-successors of its instances to be in $A_i^2$ or $A_i^2$, for all $i = 1, \ldots, k$, so all such successors are in $F^2$. It follows, by definition of $\nu$, that all the instances of $C$ belong to $\nu X.(F \land \exists R.X)$, which proves the "only if" part of the claim.

To prove the "if" part of the claim, suppose that $\phi$ is not valid, and construct a counterexample $I$ to the subsumption as follows. Let $\Delta^2$ be an infinite set $\{d_i \mid i \in N\}$. Let $F^2 = \{d_i, d_{i+1} \} \mid i \in N\}$. For all $i \in N$ and $j = 1, \ldots, k$, let $d_i \in A_j^2$ iff $i \mod p_j = 0$, and let $A_j^2 = \Delta^2 \setminus A_j^2$. Finally, for all $i = 1, \ldots, m$, let $B_i^2 = (\ell_{i,1} \land \ell_{i,2} \land \ell_{i,3})^2$ and $F^2 = \bigcup_{i=1}^{m} B_i^2$. By construction, we have both that $I$ satisfies $KB$, and $d_i \in C^2$. Moreover, since the numbers $p_1, \ldots, p_k$ that determine the behavior of $C$’s fixpoints are distinct prime numbers, the individuals $d_1, d_2, \ldots, d_m$ collectively satisfy all possible combinations of literal encodings that contain no pair of complementary concepts $A_j$ and $\neg A_j$ ($j = 1, \ldots, k$). So the concepts satisfied by $I$’s elements represent all possible truth assignments to $x_1, \ldots, x_k$. One of this truth assignments falsifies $\phi$, by assumption, so – by construction – there exists $d_i \in \Delta^2$ such that $d_i \not\in F^2$.

As a consequence, $d_i \not\in \nu X.(F \land \exists R.X)$. This proves that $C^2 \not\subseteq \nu X.(F \land \exists R.X)^2$, which completes the proof of the claim.

The reduction is correct by the claim; we are only left to show that it can be computed in polynomial time. The size of the knowledge base and the size of the concept $\nu X.(F \land \exists R.X)$ are obviously polynomial in the size of $\phi$, so we only have to provide a polynomial bound on the size of $C$. In order to see this, we use a results by Rosser (Rosser 1941). The $k^{th}$ prime number $p_k$ is bounded by $p_k < k(\log k + \log \log k + 2)$ so, for sufficiently large $k$, $p_k < 2k^2$. It follows that the length of each concept $\nu X.C_i^{p_i}$ in (1) is $O(k^2)$ and the entire concept $C$ is $O(k^3)$, so the reduction can be computed in polynomial time.

As a corollary, subsumption checking in $\mathcal{PL}_\omega^5$ is coNP-hard, even if neither disjointness axioms nor range axioms are used, and only one functional role is used.

# 4 $\mathcal{PL}$ with Universal Restrictions and Transitive Role Closure

Transitive role closure provides an alternative way of expressing sticky policies. Transitive closure can be regarded as a restricted form of fixpoint: every concept of the form $\forall R^+.C$ can be expressed with $\nu \forall R.(C \land R)$. So, reasoning in $\mathcal{PL}_\omega$ with transitive role closure might turn out to be less complex than reasoning in $\mathcal{PL}_\omega$ with greatest fixpoints. Unfortunately, tractability is not preserved, due to the interplay of $\forall$ and $\exists$. We are going to prove that the NP-complete EXACT COVER (XC) problem can be reduced.

In particular, each propositional interpretation $\{x_{i_1}, \ldots, x_{i_n}\}$ corresponds to the element $d_{x_i}$ with $h = \prod_{i=1}^{n} p_i$.

It is not hard to see that it can even be computed in logarithmic space.
to subsumption in two extensions of $\mathcal{PL}_0$ that employ the operators $\forall$ and $^+$ needed to encode sticky policies.

We prove these results by adapting a reduction of XC to concept (un)satisfiability in $\mathcal{ALE}$, extensively illustrated in (Donini 2003, Sec. 3.3.1). Let us first recall the definition of the problem:

**Definition 3 (Exact cover, XC).** Given a finite set $U = \{u_1, \ldots, u_n\}$ and a family $M = \{M_1, \ldots, M_m\}$ of subsets of $U$, decide whether there exist an exact cover of $U$, that is, a family of mutually disjoint sets $M_1, \ldots, M_m$ whose union equals $U$.

The following lemma introduces the reduction and states its correctness:

**Lemma 4.** (Donini 2003) An instance of XC has an exact cover if, and only if, the concept $C_M$ defined below is unsatisfiable:

$$C_M = C_{1}^{1} \sqcap \ldots \sqcap C_{1}^{m} \sqcap D$$

where each $C_{1}^{j}$ is inductively defined as

$$C_{2n+1}^{j} = \top \quad \text{(base case)}$$

$$C_{l}^{j} = \begin{cases} 
R.C_{l+1}^{j} & \text{either } l \leq n \land u_{l} \in M_{j} \text{ or } n < l \leq 2n \land u_{l-n} \notin M_{j} \\
R.C_{l+1}^{j} & \text{either } l \leq n \land u_{l} \notin M_{j} \text{ or } n < l \leq 2n \land u_{l-n} \notin M_{j} 
\end{cases}$$

and $D = \forall R.\forall R_{1} \ldots \forall R_{l} \bot$.

**Example 5.** Let $U = \{u_1, u_2\}$ and $M = \{M_1, M_2\}$, where $M_1 = \{u_1\}$ and $M_2 = \{u_2\}$. Concept $C_M$ is

$$\exists R.\forall R.\exists R.\forall R.\top \sqcap (C_{1}^{1}) \sqcap \forall R.\forall R.\forall R.\top \sqcap (C_{2}^{2}) \sqcap \forall R.\forall R.\forall R.\bot \quad (D)$$

Note that this instance of XC has an exact cover ($M$ itself) and $C_M$ is indeed inconsistent.

Lemma 4 was proved by showing that an exact cover exists iff the tableaux for $C_M$ has a clash, caused by a node labelled with both $\top$ and $\bot$, where $\bot$ has been introduced by some of the concepts $C_{l}^{j}$ and $\bot$ has been introduced by $D$. Clearly, the same result can be obtained by replacing $\top$ (that is not supported in $\mathcal{PL}$) with a concept name $A$. So, from Lemma 4, we get:

**Corollary 6.** Let $C_{M}^{A}$ be the concept resulting from $C_M$ by replacing each occurrence of $\top$ with concept name $A$. An instance of XC has an exact cover if, and only if, the concept $C_{M}^{A}$ is unsatisfiable.

It follows that subsumption is intractable in the extension of $\mathcal{PL}_0$ with $\forall$, that will be denoted by $\mathcal{PL}_{0}^{\forall}$.

**Corollary 7.** Subsumption checking in $\mathcal{PL}_0$ is NPhard, even if the knowledge base is empty.

**Proof.** The exact cover problem is reduced to subsumption as follows: let $A$ and $B$ two distinct concept names. For a given instance of XC, the corresponding concept $C_{M}^{A}$ and $B$ have no symbols in common, therefore $C_{M}^{A} \sqsubseteq B$ is valid iff $C_{M}^{A}$ is unsatisfiable. Then this corollary immediately follows from Corollary 6.

As a last attempt to restore tractability, one may consider another extension of $\mathcal{PL}_0$ where the problematic quantifier $\forall$ can be used only in conjunction with transitive role closure (as required by sticky policy modeling), and viceversa. In other words, expressions like $\forall R.C$ and $\exists R.C$ are permitted, while $\forall R.C$ and $\exists R.C$ are disallowed. This logic will be denoted with $\mathcal{PL}_0^{\forall,\exists}$. This attempt is motivated by the observation that if $\forall R$ were replaced with $\forall R^+$ in $C_{M}^{A}$, then the resulting concept would not capture exact covers anymore.

**Example 8.** Let $U = \{u_1, u_2, u_3\}$ and $M = \{M_1, M_2\}$, where $M_1 = \{u_1\}$ and $M_2 = \{u_2\}$. The replacement of $\forall R$ with $\forall R^+$ in $C_{M}^{A}$ yields:

$$\exists R.\forall R^+.\exists R.\forall R^+.\forall R^+.A \sqcap \forall R^+.\exists R.\forall R^+.\forall R^+.A \sqcap \forall R^+.\forall R^+.\forall R^+.\forall R^+.\bot$$

The concepts in the first two lines create an infinite sequence of $R$-successors that clashes with the concept in the third line. So the above concept is inconsistent although this instance of XC has no exact covers.

Unfortunately, the restriction on $\forall$ and $^+$ does not yield a tractable logic, either. First note that the reduction reported in Lemma 4 works equally well if different roles are used at each level, as in the following example.

**Example 9.** The concept $C_M$ illustrated in Example 5 could be equivalently replaced with

$$\exists R_{1}.\forall R_{2}.\exists R_{3}.\forall R_{4}.\top \sqcap \forall R_{1}.\exists R_{2}.\exists R_{3}.\forall R_{4}.\top \sqcap \forall R_{1}.\forall R_{2}.\exists R_{3}.\forall R_{4}.\bot$$

This version preserves the correspondence with XC stated in Lemma 4, because the tableaux produced by the two reductions have the same structure and differ only in the role names. Now each $\forall R_i$ can be equivalently replaced with $\forall R_i^+$; more precisely, it is easy to verify that also this second change preserves the structure of the tableaux for $C_M$, and that the only difference is that $\forall R_i$ is replaced by $\forall R_i^+$ in node labels.

As a consequence of the above discussion, subsumption checking in $\mathcal{PL}_0^{\forall,\exists}$ is intractable due to the following reduction from XC:

**Lemma 10.** An instance of XC has an exact cover if, and only if, the concept $C_{M}^{A}$ defined below is unsatisfiable:

$$C_{M}^{A} = C_{1}^{1} \sqcap \ldots \sqcap C_{1}^{m} \sqcap D'$$

where each $C_{1}^{j}$ is inductively defined as

$$C_{2n+1}^{j} = A \quad \text{(base case)}$$

$$C_{l}^{j} = \begin{cases} 
R_{i}.C_{l+1}^{j} & \text{either } l \leq n \land u_{l} \in M_{j} \text{ or } n < l \leq 2n \land u_{l-n} \notin M_{j} \\
R_{i}.C_{l+1}^{j} & \text{either } l \leq n \land u_{l} \notin M_{j} \text{ or } n < l \leq 2n \land u_{l-n} \notin M_{j} 
\end{cases}$$

and $D' = \forall R_{1}^+.\forall R_{2}^+.\ldots \forall R_{2n}^+.\bot$. 

The lower complexity bound (next theorem) can be proved by analogy with the proof of Corollary 7, using $C^{\nu A}$ and Lemma 10 in place of $C^{\nu M}$ and Corollary 6.

**Theorem 11.** Subsumption checking in $\mathcal{PL}_0^{\nu+}$ is NP-hard.

## 5 Towards A Tractable Approach

Here we introduce a language tailored to the encoding of sticky policies. Such a specialized approach is motivated by the intractability results proved in the previous sections. The complexity caused by the interactions between $\nu$ and $\exists$ identified in section 3 will be avoided by restricting the language so as to allow only simple, linear recursions whose cyclic behavior has period 1.

**Definition 12** (Pol,$\mathcal{PL}_0^{\text{sticky}}$). Let Pol be the least language containing:

- all the simple concepts of $\mathcal{PL}_0$ with no occurrence of sticky (called sticky-free concepts);
- all the concepts $C \cap \forall \exists$ sticky, $D$ such that $C$ is a sticky-free $\mathcal{PL}_0$ concept and $D$ a $\nu$-free concept in Pol;
- all the concepts $C \cap \nu X.\exists$ sticky, $D \cap X$ such that $C$ and $D$ are sticky-free $\mathcal{PL}_0$ concepts.

$\mathcal{PL}_0^{\text{sticky}}$ knowledge bases are $\mathcal{PL}$ knowledge bases containing only axioms from Table 2, and at least the axiom $\text{func(sticky)}$, that must also be the unique axiom where sticky occurs. $\mathcal{PL}_0^{\text{sticky}}$ subsumption queries are expressions $C \subseteq D$ where $C$ and $D$ are in Pol.

**Example 13.** The following policies are in Pol and can be used in $\mathcal{PL}_0^{\text{sticky}}$ subsumption queries:

- $\exists \text{has\_data}.\text{Contact}$
- $\exists \text{has\_processing}.\text{Transfer}$
- $\exists \text{has\_purpose}.\text{Marketing}$
- $\exists \text{sticky}.$
  - $\exists \text{has\_data}.\text{Contact}$
  - $\exists \text{has\_processing}.\text{Transfer}$
  - $\exists \text{has\_purpose}.\text{Marketing}$
  - $\exists \text{sticky}.$

$\mathcal{PL}_0^{\text{sticky}}$ subsumption checking can be reduced to the same problem in $\mathcal{PL}_0$. To see this, we first prove a lemma that considers the four possible cases in which the given $\mathcal{PL}_0^{\text{sticky}}$ subsumption contains the fixpoint operator $\nu$ (the other $\mathcal{PL}_0^{\text{sticky}}$ subsumptions are just classic $\mathcal{PL}_0$ subsumptions). Each case is reduced to a small number of $\mathcal{PL}_0$ subsumptions.

**Lemma 14.** Let KB be a $\mathcal{PL}_0^{\nu+}$ knowledge base, and let $C$, $D$, $E$, and $F$ be sticky-free Pol concepts.

1. $KB \models \nu X.\exists \text{sticky}.$ $(\nu X \subseteq E \nu X \exists \text{sticky}.$ $(F \subseteq X)$ iff some of the following conditions hold:
   - $KB \models C \subseteq D$, $C \subseteq F$
   - both $KB \models C \subseteq E$ and $KB \models D \subseteq F$

2. If $G$ is $\nu$-free, then $KB \models G \subseteq C \nu X.\exists \text{sticky}.$ $(\nu X \subseteq E)$ iff $KB \models G \subseteq D$

3. If $E$ is both $\nu$-free and sticky-free, then $KB \models C \subseteq \nu X.\exists \text{sticky}.$ $(\nu X \subseteq E)$ iff either $KB \models C \subseteq E$ or $KB \models D \subseteq F$

4. If $G$ is $\nu$-free but not sticky-free, that is,

   $$G = G_0 \nu \exists \text{sticky}.$$(G_1 \nu \exists \text{sticky}.$$(\ldots \nu \exists \text{sticky}.G_n).$$ (2)

(whose $G_0, \ldots, G_n$ are sticky-free $\mathcal{PL}_0$ concepts), then $KB \models C \subseteq \nu X.\exists \text{sticky}.$ $(\nu X \subseteq E)$ iff some of the following conditions hold:

- $KB \models C \subseteq D$
- $KB \models D \subseteq F$
- both $KB \models C \subseteq G_0$ and $KB \models D \subseteq G_1 \ldots G_n$

**Proof.** We start by proving statement 2. Since $G$ is $\nu$-free, it belongs to $\mathcal{PL}_0$, therefore – if consistent w.r.t. KB it has a finite tree-shaped model that satisfies KB (Bonatti et al. 2020). In such models, the concept on the right-hand side (that has only infinite models) is empty, so the subsumption is false. It follows easily that the subsumption holds iff $KB \models G \subseteq D$. This proves 2.

**Proof of 3.** “if”. If $KB \models C \subseteq E$, then the subsumption holds because its left-hand side is subsumed by $C$ and is not $\text{transitive}$. If $KB \models D \subseteq F$, then also $KB \models \nu X.\exists \text{sticky}.$ $(\nu X \subseteq E)$, so the subsumption holds because its left-hand side is subsumed by $F$.

**Proof of 3.** “only if”. By contraposition, assume that $KB \models C \subseteq E$ and $KB \models D \subseteq F$. Then there exist two pointed interpretations $(I_1, d_1)$ and $(I_2, d_2)$, that are models of $KB$, and satisfy the sticky-free concepts $C \subseteq \neg E$ and $D$, respectively. We may assume w.l.o.g. that $I_1$ and $I_2$ have disjoint domains. Define an interpretation $\mathcal{J}$ as the union of $I_1$ and $I_2$ extended with the following definition of sticky:

$$\text{sticky}^\mathcal{J} = \{(d_1, d_2), (d_2, d_2)\}.$$

By construction, $\mathcal{J}$ satisfies $KB$: indeed, the union of $I_1$ and $I_2$ satisfies $KB$ by the disjoint model union property (Bonatti et al. 2020), and the definition of sticky satisfies $\text{func(sticky)}$, that is, the unique axiom involving sticky in $KB$. Moreover, by construction, $(\mathcal{J}, d_1)$ satisfies the left-hand side of the subsumption but not $E$. Then $\mathcal{J}$ witnesses that the subsumption does not hold.

**Proof of 1.** The “if” part is straightforward and left to the reader. The “only if” part is proved similarly to the previous case. More precisely, by contraposition, assume that $KB \models C \subseteq D$ and $KB \models \nu X.\exists \text{sticky}.$ $(\nu X \subseteq F)$ holds. In the former case, construct a counterexample $(\mathcal{J}, d_1)$ to the subsumption by composing two models of $C \subseteq \neg E$ and $D$, respectively, as shown in the...
proof of statement 3. Similarly, in the latter case, construct a counterexample \((J, d_1)\) to the subsumption by composing two models of \(C\) and \(D \sqcap \neg F\), respectively.

**Proof of 4, “if”.** Let \(FP\) denote the fixpoint expression in the left-hand side of the subsumption, and note that the left-hand side is equivalent to:

\[
C \sqcap \exists\text{sticky}.(D \sqcap \exists\text{sticky}.(\ldots \exists\text{sticky}.(D \sqcap FP) \ldots))
\]

This makes the left-hand side directly comparable with (2). Now the “if” part is straightforward and left to the reader.

**Proof of 4, “only if”.** By contraposition, assume that \(KB \not\models C \sqsubseteq D\), \(KB \not\models D \subseteq C\), and either \(KB \not\models C \sqsubseteq G_0\) or \(KB \not\models D \subseteq G_1\) \(\ldots \sqsubseteq G_n\) holds. In the former case, obtain a counterexample to the subsumption by composing two models of \(C \sqsubseteq -G_0\) and \(D\), respectively, as shown in the proof of 3. In the latter case, there exists \(i\) \((1 \leq i \leq n)\) such that \(KB \not\models D \subseteq D_i\). Then obtain a counterexample to the subsumption by composing two models of \(C\) and \(D \sqcap -G_i\), respectively, using the same approach as in 3. \(\square\)

As a consequence of the above lemma, we get:

**Theorem 15.** Subsumption checking in \(PL^{\text{sticky}}_0\) can be done in polynomial time.

**Proof.** \(PL^{\text{sticky}}_0\) subsumption checking can always be reduced to subsumption checking in \(PL_0\). In particular, for all given \(PL^{\text{sticky}}_0\) subsumptions \(C \subseteq D\), either \(C\) and \(D\) are \(\nu\)-free (so \(C \subseteq D\) is a \(PL_0\) subsumption), or \(C \subseteq D\) falls in one of the four cases covered by Theorem 14. For each of these cases, Theorem 14 provides an equivalent set of subsumption checks that involve \(PL_0\) concepts only (as \(\nu\)-free \(PL^{\text{sticky}}_0\) concepts are \(PL_0\) concepts). Since subsumption checking in \(PL_0\) is in \(\text{PTIME}\), the same holds for \(PL^{\text{sticky}}_0\). \(\square\)

Note that, in the worst case, a subsumption check in \(PL^{\text{sticky}}_0\) is reduced to four subsumption checks in \(PL_0\), therefore \(PL^{\text{sticky}}_0\) preserves the asymptotic complexity of compliance checking in \(PL_0\).

### 6 Discussion and Related Work

The approach to sticky policies outlined in the previous section is only a first step towards a complete tractable solution. The language \(PL^{\text{sticky}}_0\) does not yet support some of the features of \(PL\), such as intervals and unions. These two features are related, because the normalization of intervals that makes \(PL\) subsumption queries interval-safe (hence tractable) introduces unions. Some of these unions may occur within the range of \(\nu\), and it is not possible – in general – to move them to the top level to reduce general policies to mere unions of Pol concepts. Therefore, it is necessary to investigate the interplay of fixpoints and unions, and its potential impact on complexity. We conjecture that – with a careful definition of \(PL^{\text{sticky}}_0\) – interval safety can still be obtained efficiently (given the natural restrictions satisfied by policies), and that the proof of Theorem 14 can be generalized to prove that tractability is preserved also in the presence of intervals and unions. Of course, the theoretical complexity analysis shall be complemented by an experimental performance evaluation to see if the ad hoc framework meets the scalability requirements of use cases.

Another limitation of the current version of \(PL^{\text{sticky}}_0\) is that a single consent policy cannot permit both finite and infinite data transfer chains at the same time (cf. Theorem 14, point 2), while in some cases it may be useful to state that any number of transfers is permitted. Thus, \(PL^{\text{sticky}}_0\) should be extended to support classes that may contain both finite and infinite chains, such as:

\[
\nu X.((\exists\text{sticky}.(C \sqcap X)) \sqcup D),
\]

where \(C\) is a policy that admits transfers and \(D\) a policy that does not admit transfers. This provides an independent motivation for introducing unions within the scope of \(\nu\).

It is not easy to turn the lower complexity bounds presented in this paper into exact characterizations. On the one hand, the extensions of \(PL\) that we considered make it possible to axiomatize complex, exponentially large structures, like those used in some proofs of PSPACE-hardness; on the other hand, the limited expressiveness of \(PL\) (and in particular the restrictions on union and negation) makes it difficult to use those structures to reconstruct the complexity results that have been proved for DLs that (unlike \(PL\)) support a full set of boolean concept operators. An additional difficulty stems from the fact that, in \(PL\)’s extensions, fixpoints and transitive role closures may occur only in the queries and cannot be used inside axioms.

The logic \(PL^{\text{sticky}}_0\) investigated in Section 4 is similar to \(FL_0\), in some respects. It has been proved in (Nebel 1990) that subsumption checking in \(FL_0\) is coNP-complete for acyclic TBoxes.

Fixpoints have been extensively investigated in the context of description logics, see for example (Calvanese, Giacomo, and Lenzerini 1999; Bonatti and Peron 2004; Bonatti et al. 2008; Lutz, Piro, and Wolter 2010; Franconi and Toman 2011). Most of these papers deal with expressive logics whose reasoning tasks are at least EXPTIME-hard (sometimes even undecidable). The only exception is (Lutz, Piro, and Wolter 2010), that proves the tractability of \(EL\) with greatest fixpoints. This logic and \(PL^{\text{sticky}}_0\) have several traits in common. The intractability of \(PL^{\text{sticky}}_0\) is due to the interplay of functionality axioms (not supported by \(EL\)) with the fixpoints occurring in the queries.

The seminal work that started the investigation of transitive role closures is (Sattler 1996). One of its results is the proof that extending \(ALC\) with transitive role closure makes concept satisfiability EXPTIME-complete. Subsumption checking has the same complexity because, in \(ALC\) and its extensions, concept satisfiability and subsumption checking are mutually reducible to each other. The complexity of transitive role closure in \(EL\) has been studied in (Haase and Lutz 2008). It is proved that subsumption checking is complete for coNP, PSPACE, and EXPTIME if TBoxes are empty, acyclic, and cyclic, respectively.
It may be interesting to investigate whether regular path queries can be used to model sticky policies. A rich set of results on nested regular path queries and low-complexity DLs can be found in (Bienvenu et al. 2014). However, this paper deals with query evaluation, while the counterpart of compliance checking (i.e. subsumption checking) is query containment.

We conclude by pointing out that the same approach adopted for data usage policies works out of the box for licenses in financial data markets, an area that has similar requirements (i.e. support to data transfers, and need for massive and reliable compliance checking, in order to reduce the risks of sanctions due to license violations). Moreover, the “Share Alike” Creative Commons licence has a transitive nature, much like sticky policies. These observations open up a brand new range of applications for $\mathcal{PL}$ and its extensions.
